Cover picture: Visualization of heparin-binding sites on type I collagen by rotary shadowing electron microscopy. Heparin-gold micelles mark heparin-binding sites near the NH₂ terminus of procollagen. Polarity of procollagen is identified by the COOH-terminal globular region. In many cases two procollagen molecules are joined by a polyvalent heparin-gold reagent at the binding site. See related article in this issue by San Antonio et al., 1179–1188.
