## Supplemental materials and methods

RNA isolation. Total cellular RNA was isolated from cells by resuspending cell pellets in Trizol reagent (Invitrogen) at a ratio of 1 ml Trizol to 106 cells. The mixture was incubated at room temperature for 5 min to allow the cellular material to fully lyse and dissolve. RNA was extracted by addition of $300 \mu \mathrm{l}$ of chloroform followed by thorough mixing. The aqueous layer was separated by centrifugation at $14,000 \mathrm{rpm}$ for 30 min followed by careful removal. RNA was then mixed with an equal volume of $70 \%$ ethanol, applied to an RNeasy column (QIAGEN), and prepared according to instructions. The eluted RNA was further isolated by ethanol precipitation in the presence of 75 mM sodium acetate and incubated at $-20^{\circ} \mathrm{C}$ for a minimum of 2 h . RNA was collected by centrifugation at $14,000 \mathrm{rpm}$ for 30 min , followed by washing in $100 \mu \mathrm{l}$ of $70 \%$ ethanol and recentrifugation. The final RNA pellet was resuspended in $50 \mu \mathrm{l}$ of nuclease-free water (Invitrogen) and examined for concentration and purity by optical density (260:280 nm ratio of 1.95 or greater).

Northern analysis. Northern analysis was performed on total cellular RNA isolated from unstimulated (day 0) and stimulated (day 2) B cells as described in the previous section. $10 \mu \mathrm{~g}$ RNA was mixed with loading dye and MOPS buffer, followed by heat denaturation at $65^{\circ} \mathrm{C}$ for 10 min . Each sample was then analyzed by agarose gel electrophoresis on a $1 \%$ denaturing agarose gel (formaldehyde denaturant). RNA was transferred to Hybond $\mathrm{N}^{+}$membranes (GE Healthcare) by capillary transfer in the presence on $10 \times$ SSC. Samples were immobilized on the membrane by cross-linking under UV light, followed by prehybridization for 3 h at $62^{\circ} \mathrm{C}$ using 6 ml of ExpressHyb hybridization buffer (Clontech Laboratories, Inc.) and denatured salmon sperm DNA (Applied Biosystems) at a final concentration of $167 \mu \mathrm{~g} / \mathrm{ml}$. DNA probes were amplified using the following oligonucleotides: I $\mu$ forward, $5^{\prime}$-CTTCCCTCTGAT-TATTGGTCTCC- $3^{\prime}$ and $\mathrm{I} \mu$ reverse, $5^{\prime}$-CCACCAACC AGCATGTTCAAC-3', creating a $245-\mathrm{bp}$ probe; C $\mu$ forward, $5^{\prime}$-GTCAGTCCTTCCCAAAT-GTCTTCC-3' and C $\mu$ reverse, $5^{\prime}$-CCTCCGTAGTGGATTTTGCATACC-3', creating a 280-bp probe; and $\beta$-actin forward, $5^{\prime}$-TACCACAGGCATTGTGATGGACTC-3' and $\beta$-actin reverse, $5^{\prime}$-GTCAGGCAGCTCATAGCTCTTCTC-3', creating a 268-bp probe. The probes were radiolabeled using a High Prime DNA labeling kit (Roche) and $50 \mu \mathrm{Ci} \alpha-\left[{ }^{32} \mathrm{P}\right]$-dCTP. Hybridization was performed by the addition of 25 ng of labeled probe to the hybridization buffer, followed by incubation at $62^{\circ} \mathrm{C}$ overnight. The membrane was then washed at $62^{\circ} \mathrm{C}$ in $2 \times$ SSC and $0.1 \%$ SDS for 30 min , followed by further washing in $0.1 \times$ SSC and $0.1 \%$ SDS for an additional 30 min . Products were visualized after exposure to phosphor imaging screens, and analysis was done using a Typhoon TRIO+ (GE Healthcare) imaging instrument using ImageQuant 5.2 software (GE Healthcare).

Figure S1. Model to compare the retardation of RNA polymerases in ChIP versus nuclear run-on assays. The ChIP assay depicts the loading of RNA pol II (numbered red circles) at a given instant. Pols 4 and 5 are twice as dense as pols 1-3 because they slow down when reaching R-loops around the repetitive region. Polymerases in the repetitive region (dotted circles) are very dense because of difficulty in unwinding RNA-DNA hybrids formed by the polymerases ahead of them. After the repetitive region, the polymerases move faster. The nuclear run-on assay depicts the activity of these polymerases after initiation of transcription in vitro for 30 min . No new polymerases are loaded, and all existing polymerases move forward. Pols $2-5$ pile up at the beginning of the repetitive region, and pols 6-9 come from within the repetitive region. Both these groups have increased labeled transcripts because they are in high density.

B

Figure S2. Contribution of VDJ and $1 \mu$ promoter activities to $S \mu$ transcription in Ung ${ }^{-/-}$B cells. (A) Total RNA per cell was measured by optical density. Error bars represent the SD of values from two experiments with two mice and three mice. (B) Northern analysis. Labeled probes were hybridized to blots containing $10 \mu \mathrm{~g}$ RNA per lane from three individual mice. Two experiments with three mice each were performed. Specific transcripts were detected by probes for $1 \mu$ spliced transcripts ( 2.1 kb ), $C \mu$ spliced transcripts derived from promoters for VDJ ( 1.7 kb ) and l $\mu$, and $\beta$-actin transcripts ( 2 kb ). The l $\mu$ blot was exposed for 24 h , and the $\mathrm{C} \mu$ and $\beta$-actin blots were exposed for 1 h . $\mathrm{l} \mu$ transcripts were not visible on the $C \mu$ blot because $l \mu$ was less abundant and required longer exposure. The decrease in $1 \mu$ transcripts on day 2 could be explained by the fact that there is more RNA per cell after activation (A), so that $10 \mu \mathrm{~g}$ RNA on day 2 would derive from fewer cells than $10 \mu \mathrm{~g}$ collected on day 0.

Figure S3. Location of mutations in the $\mathrm{S} \mu$ region. Every 10th base is underlined. EcoRI and HindIII sites are shown in bold. Allelic differences are noted in yellow, with C57BL/6 shown below the 129SV germline sequence. Mutations are placed above the germline sequence. $\Delta$, deletion; ^, insertion. 1,241 bases in the repetitive region were not sequenced.

S1, 513 bp ( 143 clones, 29 mutations)

| To |  | A | T | G | C | Total |
| :--- | :--- | :--- | :--- | :--- | :--- | :---: |

## S8, 436 bp (91 clones, 0 mutations)

Figure S4. Types of substitutions in the $\mathrm{S} \mu$ region from $\mathrm{Ung}^{-/-}$mice. Mutations were recorded from the nontranscribed strand and have been corrected for base composition of the nucleotide sequence. Data are expressed as percent of the number of mutations. The nucleotide composition of each fragment is as follows: S1: 32\% A, 30\% T, 21\% G, and $17 \%$ C; S2: $25 \%$ A, $36 \%$ T, $19 \%$ G, and $20 \%$ C; S3: $28 \%$ A, $32 \%$ T, 22\% G, and $18 \% ~ C ; ~ S 4: 34 \% ~ A, ~$ $25 \%$ T, $26 \%$ G, and $15 \%$ C; S5: 29\% A, 23\% T, $29 \%$ G, and $19 \%$ C; S7: $22 \%$ A, $23 \%$ T, $39 \%$ G, and $16 \%$ C; $58: 25 \%$ A, $24 \%$ T, $35 \%$ G, and $16 \%$ C. The increase in mutations of T in S 7 is the result of repeated mutations at a hot spot. S 8 had no mutations.

Figure S5. Model of hypermutation and transcription in the $S \mu$ region. (A) The 5-kb region is shown that encodes $E \mu$, $1 \mu$, the repetitive region (RR), and the first exon of $\mathrm{C} \mu$. The oval depicts the region that forms R-loops (Huang, F.T., K. Yu, B.B. Balter, E. Selsing, Z. Oruc, A.A. Khamlichi, C.L. Hsieh, and M.R. Lieber. 2007. Mol. Cell. Biol. 27:5921-5932). (B) The mutational map from Fig. 3 A is shown. (C) The relative frequency of RNA pol II molecules detected in this study is shown as gray circles. (D) Model for distribution of enzymes in the $S \mu$ region. circles, RNA pol II; AID, stars; and ovals, DNA pol $\eta$. AID may associate with RNA polymerases as they move through $S \mu$. RNA pol II molecules accumulate at the beginning of the R-loop, and move slowly though the complexed RNADNA hybrids, as AID binds to single-strand DNA and initiates mutation. At the end of the repetitive region, AID dissociates from the transcription complex and mutation stops. RNA pol II then progresses more rapidly to the $C \mu$ gene. DNA pol $\eta$ is only active in the region before R-loops.

Table S1. Primers for sequencing and run-on assays

| Region | Oligonucleotide ( $5^{\prime} \rightarrow 3^{\prime}, 5^{\prime}$ overhang in lower case) |
