

General Physiology is the study of biological mechanisms through analytical investigations, which decipher the molecular and cellular mechanisms underlying biological function at all levels of organization.

The mission of *The Journal of General Physiology* is to publish articles that elucidate important biological, chemical, or physical mechanisms of broad physiological significance.

Communication

- 109 A marginal band of microtubules transports and organizes mitochondria in retinal bipolar synaptic terminals. Malcolm Graffe, David Zenisek, and Justin W. Taraska

Cover picture: A 3-D projection of a single isolated goldfish retinal bipolar cell stained with the live-cell microtubule dye SiR-tubulin. The color spectrum represents depth. Microtubules can be seen to extend from the tips of the dendrites (top) into the axon and down into the giant synaptic terminal (bottom). A loop of microtubules encircles the inner plasma membrane of the terminal and anchors mitochondria (see Communication by Graffe et al., 109–117).
